

Java has its own way of producing output just as any other programming languages. In Java, the `System.out.print` statement is used for output.

For example:

```
System.out.print("Hello, Java!");
```

This simple statement then outputs:

Hello, Java!

The print statement also has different variations depending on the program you are writing.

- **System.out.print()** - outputs on the same line
- **System.out.println()** - creates a newline after output
- **System.out.printf()** - can be used to format strings

Below is an example of the `println()` method to output the string: "My First Java Application."

Syntax for `System.out.printf()` - use format specifiers to print variables within the string based on their data type

- `%d` - int
- `%s` - String
- `%f` - float and double
- `%b` - boolean
- `%c` - char

Ex.)

```
int number = 1;
```

```
System.out.printf("Number: %d",num);
```

```
String str = "Hello"
```

```
System.out.printf("Greeting: %s",str);
```

```
double decimal = 1.20;
```

```
System.out.printf("Decimal Number: %f",decimal);
```

```
boolean status = true;
```

```
System.out.printf("True or False: %b",status);
```

```
char character = 'Z';  
System.out.printf("Last letter of the alphabet: %c",character);
```
